The transtibial amputation is a preferred procedure for the upper and lower limbs due to the preservation of the flexion-extension axis and the patellar function, but it has the disadvantages of using very short lever arms and of resection of the distal part of the tibia. A novel approach of using a retro-femoral fixation with the tibia prosthesis is presented in this article. We performed 22 transfixations using polymethylmethacrylate (PMMA) plates in 14 patients. Mean follow-up was 25.3 months. Clinical and functional results of the patients were satisfactory. No systemic or local infection and implant failure were observed in this group. The most common complication was loosening of the prosthesis (13 cases). In five cases, the plate had to be removed and the osteosynthesis was performed using tension-band wiring in three, tension-band wiring with a bone graft in one and cerclage in one. No infection was observed in these cases. In one case the plate was broken in the first follow-up. According to the results, we recommend that transfixation using a retro-femoral-tibial fixation should be considered as an alternative for the treatment of patients with advanced knee osteoarthritis.Main menu Post navigation Review of the Documentary, The American Dream If you ask a young person, if they believe in the American Dream, you will often get the answer "No, I'm tired of it."
